

Lab H External Hardware Interrupts

1. Assemble the following circuit:

```

;Delay Subroutine
Delay:   ORG           250H
         NOP
         MOV           TMOD,#01H
         MOV           TL0,#00H
         MOV           TH0,#00H
         SETB         TR0
Red:     NOP
         JNB          TF0,Red
         CLR          TR0
         CLR          TF0
         RET
         END
    
```

3. Refer to the various tables in Ch. 11 and add another interrupt at Int0. This interrupt must work in reverse of Int1. This new interrupt will require another push button circuit.

2. Create the following program and add appropriate comments:

```

ORG           00H
AJMP         Main

;Interrupt Vector
ORG           013H
ACALL       Spin
CLR         TF0
SETB       TR0
RETI

Main:       ORG           100H
           NOP
           SETB         TCON.2 ;Int1, falling edge
           MOV          IE,#84H ;enable interrupt 1
Loop:      MOV          P1,A
           ACALL       Delay
           CPL          A
           SJMP       Loop

;Interrupt Subroutine
Spin:     ORG           200H
           MOV          R0,#10H
           MOV          A,#80H
           MOV          P1,A
           ACALL       Delay
Blue:    RR            A
           MOV          P1,A
           ACALL       Delay
           DJNZ        R0,Blue
           MOV          A,#00H
           MOV          P1,A
           RET
    
```

4. Draw the new circuit.

5. New commands or registers:

RETI - return from interrupt

TCON - timer/counter register

IE - interrupt enable registers
